

## FINDING THE PERFECT ANCHOR POINT

Changing from a string peep to the Anchor Sight is best done using the following method:

If you have used a peep sight for a long time you have been forced to establish your anchor point by leaning over the string. The key to shooting in a hunting environment is having an anchor point that gives you the most consistency, feels right and is torque free. Remember, the purpose of the anchor point is to position one's eye in exactly the same spot every time while not putting torque on the bow. For many shooters, the anchor point dictated by a string peep is **not** a good one for holding the bow without torque.

Finding your perfect anchor point using the Anchor Sight can be done using the following method:

Install the Anchor Sight frame only, then move your front pin out 1/8 inch to compensate for the frame thickness. Without using the Anchor sight, sight in your front pins on a target, at say 10 yards, using only the anchor point you come back to naturally. Shoot until you have established a grouping and feel you have found your natural anchor point. Get your groups on the bullseye of the target by moving your front pin. Now, sight the Anchor sight to your eye at that new anchor point. When you are comfortable with the alignment start shooting using the Anchor Sight. More likely than not you will see your groupings go slightly off target because you did not get the Anchor sight perfectly aligned to your new anchor point. To do this you simply move the arrow group on the bullseye by using the Micro adjustments.

If you are right handed... and the group is off to the left of the bullseye, you turn the side (horizontal) Micro screw clockwise until the group moves on target. If you are low, turn the Vertical Micro clockwise and your arrow should go up. When the arrows group on the bullseye, you have gotten back to the exact anchor point (eye position) you had chosen.
